County population estimates by age, race and sex: April 1, 1982

Marylou Mandell, Assistant in Research

P·S·
Population Studies

The estimates published in this bulletin were derived from a technique combining the housing-unit method of total population estimation and the cohort-component method of estimating the age, sex and race distribution of the total population. The base data were taken from the 1970 and 1980 censuses of population conducted by the U.S. Bureau of the Census. The 1980 race data have been adjusted to make the white-nonwhite categories consistent for 1970 and 1980. Medicare data have been used to estimate the population age 65 and older.

The basic methodology for these estimates is as follows: 1970 and 1980 population data were compiled for each county by five-year age groups for white and nonwhite males and females. Ratios were made for each age group in 1980 to the age group ten years younger in 1970 (e.g., 20-24 in 1980 to 10-14 in 1970). This procedure was done for both sexes and both racial categories, thereby providing estimates of the percentage change in each age group by sex and race. These ratios were adjusted to provide two-year rather than ten-year changes, and were applied to each age/sex/race category in 1980. This process provided a 1982 estimate of the population older than age two by age, sex and race. The 1980 child-woman ratio was used to estimate the births, deaths and migration of children less than age two. Medicare data were used to estimate the population age 65 and older. The estimates of the age, sex and race components of the population were then adjusted to add to the 1982 estimates of total population published by the Bureau of Economic and Business Research.

The estimates published in this bulletin cover only certain broad age groups (0-14, 15-24, 25-44, 45-64, 65+ and 18+). Data for five-year age groups are available from the Bureau of Economic and Business Research for a nominal fee. For further information please contact the Bureau at 221 Matherly Hall, University of Florida, Gainesville, Florida 32611.

Bulletin No. 66 **December, 1983**

This public document was promulgated at an annual cost of $177.15 or $0.12 per copy to make available information about population in Florida. The sales cost of this publication was set to cover the total cost of producing it. The "annual cost" to the Bureau shown above is only that part of the cost paid out of state funds.

Number of households and average household size in Florida: April 1, 1983

Stanley K. Smith, Population Program Director

and

Faith Sincich, Assistant in Research

This publication shows the number of households and average household size for Florida and each of its counties for 1970, 1980 and 1983. Households are defined as housing units occupied by permanent residents. They should not be confused with total housing units, which include vacant and seasonally occupied units as well as units occupied by permanent residents. According to the United States Bureau of the Census, a person is classified as a permanent resident of "...his usual place of residence, which is generally construed to mean the place where he lives and sleeps most of the time. This place is not necessarily the same as his legal residence, voting residence or domicile." The numbers shown in this bulletin refer only to the number of households and average household size of permanent Florida residents.

Data for 1970 and 1980 were taken from actual census counts conducted by the United States Bureau of the Census. Data for 1983 were taken from estimates produced by the Bureau of Economic and Business Research. Estimates of households were based on electric customer and building permit data (primarily the former). Estimates of average household size were based on each area's average household size in 1980, the national decline in average household size since 1980 and the local change in housing mix since 1980. A more detailed description of the methodology used to estimate households and average household size can be found in "Some New Techniques for Applying the Housing Unit Method of Local Population Estimation," Demography, Volume 17, Number 3, August, 1980.

Number of households

There were 4,135,881 permanent households in Florida on April 1, 1983. This represents an increase of almost 400,000 since 1980, or 10.5 percent. Dade's 638,600 households in 1983 were far more than any other county. Next in line were Broward with 451,900, Pinellas with 342,400, Palm Beach with 270,500, Hillsborough with 261,600 and Duval with 219,700. The counties with the smallest number of households were Lafayette with 1,500, Liberty with 1,600, Gilchrist and Union with 2,300 and Glades with 2,400.

Palm Beach has had the largest increase in number of households since 1980, growing by 36,100. Other large increases

Bulletin No. 67

February, 1984

This public document was promulgated at an annual cost of $177.15 or $0.12 per copy to make available information about population in Florida. The sales cost of this publication was set to cover the total cost of producing it. The "annual cost" to the Bureau shown above is only that part of the cost paid out of state funds.

occurred in Broward (34,400), Dade, (28,800), Hillsborough (23,600) and Pinellas (22,900). In terms of percentage increases, the number of households grew most rapidly in Osceola County (33 percent), followed by Hernando (30 percent), Flagler (30 percent), St. Lucie (24 percent) and Collier (23 percent). No county in Florida experienced a net loss in households between 1980 and 1983, but the increases were less than 100 in Calhoun, Liberty and Lafayette counties.

Average household size

Average household size in Florida declined from 2.90 to 2.55 between 1970 and 1980. This rapid decline of 12.1 percent was caused by falling birth rates, increasing divorce rates, the heavy inmigration of older persons and the growing tendency for single persons to live alone. Since 1980 the trend toward smaller average household size has continued, but the decline has been much smaller. At the state level, average household size fell from 2.55 to 2.51 between 1980 and 1983 for a decline of only 1.6 percent. Birth rates have increased slightly since 1980 and the severe economic recession of 1981-1982 may have prevented some people from moving out of their existing households to form new ones. The heavy influx of Cuban and Haitian immigrants in 1980 was also a factor, as many of these immigrants moved in with friends and relatives. Every county in Florida experienced at least a small decline in average household size between 1980 and 1983 except Dade, where the concentration of foreign immigrants was strongest and average household size rose by almost 2 percent.

Average household size in 1983 was largest in Gadsden County with 3.15. Other counties with large average household sizes were Baker with 3.12, Hendry with 2.99, Clay and Hardee with 2.97 and Jefferson with 2.95. The counties with the smallest average household size were Sarasota and Pinellas with 2.21, followed by Charlotte with 2.23 and Monroe and Pasco with 2.30. Average household size is generally higher for black than white households and for younger than older households. While there is not a perfect correlation, the counties in Florida with a large average household size tend to have relatively high proportions of black households, while counties with a small average household size tend to have relatively high proportions of older persons.

Projections of Florida population by county

1985-2020

Stanley K. Smith
Population Program Director
and
Faith Sincich
Assistant in Research

P.S. Population Studies

People are fascinated by the future. Palm readers, astrologers and crystal ball gazers down through the centuries have found eager buyers for their predictions. Modern-day researchers and forecasters, using computers and large-scale models, continue to find willing audiences. There is particularly great interest in population projections, and, for good reason: many types of public and private planning--for schools, hospitals, stores, houses, service stations, roads and countless other projects--require some information on future population trends. Yet the future is essentially unknowable. No matter how scientific and sophisticated our projection techniques, we cannot perfectly predict future population trends. In spite of years of developing high-quality data, statistical techniques and computer programs, we still cannot "see" into the future.

We are not completely lost, of course. We can observe population trends that have occurred in the past. We can collect data and build models based on historical trends and relationships. We can then make projections from these models showing what would happen if past trends continued or varied in some particular way. Since the future is intimately tied to the past, these projections will often provide reasonably accurate forecasts of future population change. If constructed and interpreted properly, population projections--although certainly not perfect predictions of the future--can be extremely useful tools for planning and policy analysis.

The projections published in this bulletin are for the permanent resident population of Florida; they do not include tourists or part-time seasonal residents. Since the future cannot be predicted with absolute certainty, we have produced three sets of projections: low, medium and high. We believe the medium projection is more likely to provide an accurate forecast of future population change than either the low or high projections. The low and high projections, however, provide an indication of the range in which the future population might lie. While these projections provide useful benchmarks for planning and policy analysis, they should not be interpreted as the only possi-

Bulletin No. 68 **April, 1984**

This public document was promulgated at an annual cost of $177.15 or $0.12 per copy to make available information about population in Florida. The sales cost of this publication was set to cover the total cost of producing it. The "annual cost" to the Bureau shown above is only that part of the cost paid out of state funds.

ble scenarios for future population change. Other sources of information at the local level should be considered when using the projections for planning purposes (particularly for small counties).

State projections

State projections are made using the cohort-component technique. The starting point is the Florida population by age and sex, as counted by the United States Bureau of the Census on April 1, 1980. This base population is survived forward by applying survival rates to each male and female age cohort. These survival rates are based on Florida Life Tables for 1980 (Department of Health and Rehabilitative Services, Public Health Statistics Section, Jacksonville). The life table survival rates are adjusted upward in 1990, 2000 and 2010 to take account of expected increases in longevity. These adjustments are based on projections of survival rates for the United States population (U.S. Bureau of the Census, Current Population Report, Series P-25, No. 601, October 1975). The application of survival rates provides a projection of the Florida population in the absence of births and migration.

Net migration is the difference between the number of people moving into an area and the number moving out. Estimates of net migration into Florida between 1970 and 1980 were made for each age-sex group using the 1970 and 1980 censuses and Florida survival rates. These ten-year net migration estimates were transformed into rates by dividing the net migration number for each age-sex group by the number of people in the United States in the same age-sex group. Projections of net migration are produced by multiplying these net migration rates by the middle series projections of the United States population at the beginning of each projection period (U. S. Bureau of the Census, Current Population Reports, Series P-25, No. 922, October 1982).

The application of survival and migration rates to the 1980 population gives 1990 projections of the population age 10 and older. The population less than age 10 is projected by applying the child/woman ratio derived from 1980 census data (i.e. children less than age 10/women age 20-39). This represents a continuation of the age-specific birth rates from the 1970s and implies an average of approximately 1.9 births per woman over the reproductive lifetime. The population less than age 10 is divided into males and females according to historic data: 51 percent male and 49 percent female. The population less than age 10 is divided into five-year age groups by applying the age distribution for the appropriate year from U.S. population projections.

Natural increase (the difference between the number of births and the number of deaths) is very small in Florida, accounting for less than 10 percent of population growth. Reasonable variations in birth and death assumptions therefore have very little impact on total population change. Net migration, on the other hand, has a major impact and is subject to large changes over time. During the 1970s net migration was greater than 400,000 some years and less than 150,000 other years. Since net migration is such a large and volatile component of Florida population growth we have applied three different migration assumptions, giving rise to three different sets of population projections. The low assumption implies net migration of around 150,000 per year, similar to the numbers prevailing during the 1960s and several of the slow-growth years of the mid-1970s. The high assumption implies net migration of 280,000 to 370,000 per year, similar to the numbers prevailing during the rapid-growth years of the early 1970s. The medium assumption implies net migration of 240,000 to 260,000 per year, roughly the average during the entire decade of the 1970s.

The projections are made in ten-year intervals, following the techniques described above. Each projection serves as the base population for the following projection. Projections for mid-decade years (e.g. 1985, 1995) are made by means of linear interpolation. The 1985 projection is adjusted to fit with the Florida population forecast by a multi-equation econometric model (University of Florida, Bureau of Economic and Business Research, The Florida Outlook, Fourth Quarter, 1983).

County projections

While the cohort-component technique is a good way to make projections at the state

level, it is not necessarily the best way to make projections at the county level. Many counties in Florida are so small that the number of persons in each age-sex category is inadequate for reliable cohort-component projections. Furthermore, county growth patterns are so volatile that a single technique based on the 1970-1980 time period may provide misleading results. We believe more useful projections can be made if a number of different techniques and historical time periods are used.

For counties we make ten projections, using six different techniques and three different time periods. The starting point for each projection is the 1983 population estimate published by the Bureau of Economic and Business Research. Three projections are made using linear extrapolation, one using a base period of 1970-1983, one using 1975-1983 and one using 1980-1983. One projection is based on the linear regression of population on time, using annual data from 1970 to 1983. One projection is made on the linear regression of population on time and time squared, using annual data from 1975 to 1983. One projection is made by applying the average annual growth rate from 1975 to 1983. Three projections are made using a share-of-growth technique in which it is assumed that each county's share of the state's future population growth will be the same as it was during the base periods of 1970-1983, 1975-1983 and 1980-1983. One projection is made using a shift-share technique in which it is assumed that each county's share of state population will change annually by the same linear amount as the average annual change between 1970 and 1983.

These techniques provide ten different sets of projections for each county. For 1985 and 1990 the medium projection is based on the average of these ten projections. For 1995, 2000 and 2005 the medium projection is made by excluding the two highest and two lowest projections (thereby excluding techniques that tend to "explode" upward or downward when carried too far into the future) and taking the average of the six remaining projections. Our research has shown that taking the average of a number of different projections reduces the chances of making large errors and leads to more reliable projections. For the years from 2010 to 2020 we hold each county's share of state population at the same level as 2005. We believe that the continued extrapolation of past trends this far into the future is likely to be counter-productive. Some counties will grow more rapidly than the state as a whole, while others will grow more slowly. Unfortunately there is no way to know which counties will fall into which of these two categories. Consequently we take a middle-of-the-road approach and hold shares constant.

In a number of counties we make special adjustments to the population before applying the techniques described above. This is done to account for such special populations as university students, military personnel or prison inmates. Adjustments are made for counties in which these special populations account for a large proportion of total population or where the special populations have moved counter to trends for the rest of the population. In the present set of projections adjustments were made for Alachua, Baker, Bradford, Brevard, Dade, Duval, Gadsden, Jackson, Monroe, Leon, Santa Rosa and Union counties.

The techniques described above are used to make the medium set of population projections. This is the set we believe is most likely to provide an accurate forecast of future population. In all cases medium county projections are controlled to add to the state medium projection. We have also made a low and high set of projections to provide an indication of the potential variation around the medium projection. The low and high projections are based on an analysis of the errors observed when the projection techniques were applied to historic data. Although the analysis is still preliminary, we believe there is roughly a 67-percent probability that future populations will fall between the low and high projections.

Note: For the medium series, the sum of the county projections equals the state projection for each year (except for slight differences due to rounding). For the high and low series, however, the sum of the county projections does not equal the state projections. This occurs because potential variation around the medium projection is much greater for counties (especially small counties) than for the state as a whole.

Population projections by age and sex: Florida counties, 1985-2000

Stanley K. Smith
Population Program Director
and
Faith Sincich
Assistant in Research
Bureau of Economic and Business Research
University of Florida

P.S. Population Studies

Projections of total population are valuable tools for planning and policy analysis, but there are circumstances in which such projections do not provide sufficient information. Many types of planning and analysis require projections for particular subgroups of the population. How many older persons are there likely to be in 1990 and 2000? How many children? How many women of childbearing age? How many men and women of labor-force age?

It is to answer questions like these that projections by age and sex were made for Florida and each of its sixty-seven counties. This bulletin provides a summary of these projections and a brief description of the methodology used to produce them. More detailed projections (i.e. by five-year age groups up to age 85+) and a more detailed description of the methodology are available from the Bureau of Economic and Business Research.

State projections. State projections were made using a cohort-component technique in which births, deaths and migration were projected separately for each age-sex group in the population. The starting point was the Florida population by age and sex, as counted in the 1980 census. This population was survived forward using Florida survival rates by age and sex. Migration was accounted for by estimating net migration between 1970 and 1980 for each age-sex group, calculating migration rates based on the size of the United States population in 1970, and applying those rates to each age-sex group in the United States population in 1980. Projected net migration was then added to the surviving Florida population to give the projected population age 10 and older. Children younger than age 10 were projected by applying the 1980 child/woman ratio (i.e. children younger than age 10/females age 20-39) to the projected female population age 20-39. This represents a continuation of the age-specific birth rates from the 1970s and implies an average of approximately 1.9 births per woman over the reproductive life cycle. The population younger than age 10 was divided into males and females according to historic data: 51 percent male and 49 percent female (Continued on back page).

Bulletin No. 69

July, 1984

This public document was promulgated at an annual cost of $177.15 or $0.12 per copy to make available information about population in Florida. The sales cost of this publication was set to cover the total cost of producing it. The "annual cost" to the Bureau shown above is only that part of the cost paid out of state funds.

County projections. County projections were made in a manner very similar to that used for state projections. The starting point was the 1980 census count for each county by age and sex. Florida survival rates were applied to each age-sex group, providing a projection of surviving county population. Net migration between 1970 and 1980 was estimated for each age-sex group of each county, and was divided by Florida net migration between 1970 and 1980 for the same age-sex groups. This gave the proportion of Florida net migration accounted for by each county, for each age-sex group. These proportions were then applied to projected net migration for the state, providing projections of net migration by age and sex for each county. Projections of net migration were added to the surviving county population, giving the projected population age 10 and older. Children younger than age 10 were projected by applying the 1980 child/woman ratios calculated for each county, and were divided into males and females by multiplying by 0.51 and 0.49 respectively.

Adjustments were made in a number of counties to account for special circumstances. In ten counties (Alachua, Bradford, Duval, Escambia, Gadsden, Monroe, Leon, Okaloosa, Santa Rosa, Union) adjustments were made to account for large institutional populations (universities, prisons, military bases, state hospitals). In Dade County, an adjustment was made for the 90,000 Cubans and Haitians who entered in 1980. In Brevard County, the age distribution of net migration was based on that of Volusia County because of the unusual nature of Brevard's net migration during the 1970s. In all counties, the projections were controlled to add up to the total population projected by the medium series in Population Studies, Bulletin Number 68, April, 1984.

Note: Projections of the population by five-year age groups up to age 85+ are available for males, females and total population. Please contact the Bureau of Economic and Business Research for further information.

Projections of black population by age and sex: Florida counties, 1985-2000

Stanley K. Smith
Population Program Director
and
Faith Sincich
Assistant in Research
Bureau of Economic and Business Research
University of Florida

P.S. Population Studies

The 1980 census counted more than 1,342,000 black persons as permanent residents of the State of Florida. This was a large increase over the 1,041,000 counted in 1970. In 1980, blacks accounted for 13.8 percent of Florida's total population. In a number of counties, this proportion was much higher. In Gadsden County, for example, blacks accounted for 60 percent of total population in 1980. In thirteen counties, blacks made up more than one-fifth of total population in 1980.

Many types of planning and analysis require projections of the black population. This bulletin presents a condensed tabulation of projections of the black population, by age and sex, for each county and the State of Florida. More detailed projections (i.e. by five-year age groups up to age 85+) are available from the Bureau of Economic and Business Research.

The classification of persons as "black" reflects the self-identification of respondents in the 1970 and 1980 censuses. It does not denote any clear-cut scientific definition of biological stock. It includes all persons who indicated their race as black or negro, as well as persons who did not classify themselves in one of the specific race categories listed on the questionnaire, but reported entries such as Haitian, Nigerian or West Indian.

State projections. State projections were made using a cohort-component technique in which births, deaths and migration were projected separately for each age-sex group in the population. The starting point was the black population of Florida by age and sex, as counted in the 1980 census. This population was survived forward using 1980 age- and sex-specific survival rates for the black population of Florida. Migration was projected by estimating net migration between 1970 and 1980 for each age-sex group; calculating migration rates based on the size of each age-sex group in the black population of the United States in 1970; and applying those rates to each age-sex group in the black population of the United States in 1980. Projected net migration was then added to the surviving black population of Florida to give the projected black population age 10 and older. Children younger than age 10 were projected by applying the 1980 child/woman ratio for blacks (i.e. children younger than age 10/females age 20-39) to the projected number of black females age

Bulletin No. 70 August, 1984

This public document was promulgated at an annual cost of $177.15 or $0.12 per copy to make available information about population in Florida. The sales cost of this publication was set to cover the total cost of producing it. The "annual cost" to the Bureau shown above is only that part of the cost paid out of state funds.

20-39. This represents a continuation of the age-specific birth rates from the 1970s. The population younger than age 10 was divided into males and females according to historic data: 51 percent male and 49 percent female.

The techniques described above provide projections of the black population by age and sex for 1990. The same steps were repeated to give projections for 2000, using 990 instead of 1980 as a base year. Projections for 1985 and 1995 were obtained by interpolating between the projections for the other years.

County projections. County projections were made in a manner very similar to that used for state projections. The starting point was the 1980 census count of the black population of each county, by age and sex. Survival rates for Florida's black population were applied to each age-sex group, providing a projection of surviving county population. Net migration between 1970 and 1980 was estimated for each age-sex group of each county, and was divided by the net migration between 1970 and 1980 for the same age-sex groups for the entire state. This gave the proportion of Florida's total net migration of blacks that was accounted for by each county, for each age-sex group. These proportions were then applied to the projected net migration of blacks for the state, providing projections of net migration of blacks by age and sex for each county. Projections of net migration were added to the surviving county population, giving the projected population age 10 and older. Children younger than age 10 were projected by applying the 1980 child/woman ratios for the black population of each county, and were divided into males and females by multiplying by 0.51 and 0.49 respectively. These techniques were applied twice to give projections for 1990 and 2000; projections for 1985 and 1995 were obtained through interpolation.

Adjustments were made in a number of counties to account for special circumstances. In ten counties (Alachua, Bradford, Duval, Escambia, Gadsden, Monroe, Leon, Okaloosa, Santa Rosa, Union) adjustments were made to account for large institutional populations (universities, prisons, military bases, state hospitals). In Dade County, an adjustment was made for the Cubans and Haitians who entered in 1980. In Brevard County, the age distribution of net migration was based on that of Volusia County because of the unusual nature of Brevard's net migration during the 1970s.

Note: Projections of the black population by five-year age groups up to age 85+ are available for males, females and total population. Please contact the Bureau of Economic and Business Research for further information.
